**【DOCUMENT TITLE】 SPECIFICATION**

**【TITLE OF INVENTION】** METHOD OF MEASURING PYROPHOSPHATE, DEVICE FOR MEASURING PYROPHOSPHATE, METHOD OF DISCRIMINATING BASE TYPE IN A BASE SEQUENCE OF NUCLEIC ACID, DEVICE FOR DISCRIMINATING BASE TYPE, METHOD OF DETECTING NUCLEIC ACID, AND CHIP FOR INTRODUCING SAMPLE SOLUTION

**【CLAIMS】**

**【Claim 1】** A method of measuring pyrophosphate which comprises:

the step (a) of allowing a first solution containing pyrophosphate to be reserved in a first region among the first region and a second region provided by comparting with a membrane that retains  $H^+$ -pyrophosphate and hardly permeates  $H^+$  so as to bring said first solution into contact with said  $H^+$ -pyrophosphate, and allowing a second solution to be reserved in said second region; and

the step (b) of measuring alteration of the  $H^+$  concentration of either one of said first solution and said second solution,

said method characterized in that an active site that hydrolyzes pyrophosphate of said  $H^+$ -pyrophosphate is exposed to said first region.

**【Claim 2】** The method of measuring pyrophosphate according to claim 1 wherein

said membrane retains another  $H^+$ -pyrophosphate, and the active site that hydrolyzes pyrophosphate of said another  $H^+$ -pyrophosphate is exposed to said second region,

the concentration of pyrophosphate of said second solution is lower than the concentration of pyrophosphate of said first solution.

**【Claim 3】** The method of measuring pyrophosphate according to claim 1 or 2 wherein

alteration of the  $H^+$  concentration of either one of said first solution and said second solution is optically measured in said step (b).

**【Claim 4】** The method of measuring pyrophosphate according to claim 3 wherein

a pH sensitive pigment or a membrane potential sensitive pigment is added to either one of said first solution and said second solution in said step (a).

**【Claim 5】** The method of measuring pyrophosphate according to claim 4 wherein

acridine orange or Oxonol V is added to either one of said first solution and said second solution in said step (a).

**【Claim 6】** The method of measuring pyrophosphate according to claim 1 or 2 wherein

alteration of the  $H^+$  concentration of either one of said first solution and said second solution is electrically measured in said step (b).

**【Claim 7】** A device for measuring pyrophosphate which comprises:

a vessel;

an internal chamber provided in said vessel;

a  $H^+$  hardly permeable membrane that comparts inside of said vessel into an internal region and an external region of said internal chamber for reserving a solution;

an electrode that is provided such that it is brought into contact with a solution reserved in said external region of said internal chamber; and

a  $H^+$  sensitive electrode provided such that it is brought into contact with a solution reserved in said internal region of said internal chamber,

said device characterized in that said membrane retains  $H^+$ -pyrophosphatase such that the active site that hydrolyzes its pyrophosphate is exposed to said external region.

**【Claim 8】** A method of discriminating a base type in a base sequence of a nucleic acid which comprises:

the step (a) of preparing a solution containing a nucleic acid, and a primer having a base sequence that includes a complementary binding region which complementarily binds to said nucleic acid to prepare a reaction solution by carrying out an extension reaction of said primer;

the step (b) of allowing a first solution prepared from said reaction solution containing pyrophosphate produced when the extension reaction of the primer is caused in said step (a) to be reserved in among a first region and a second region provided by comparting with a membrane that retains  $H^+$ -pyrophosphate and hardly permeates  $H^+$  so as to bring said first solution into contact with said  $H^+$ -pyrophosphate, and allowing a second solution to be reserved in said second region; and

the step (c) of measuring alteration of the  $H^+$  concentration of either one of said first solution and said second solution,

said method characterized in that an active site that hydrolyzes pyrophosphate of said  $H^+$ -pyrophosphate is exposed to said first region.

**【Claim 9】** The method of discriminating a base type in a base sequence of a nucleic acid according to claim 8 wherein

said membrane retains another  $H^+$ -pyrophosphate,

the active site that hydrolyzes pyrophosphate of said another  $H^+$ -pyrophosphate is exposed to said second region, and

the concentration of pyrophosphate of said second solution is lower than the concentration of pyrophosphate of said first solution.

**【Claim 10】** The method of discriminating a base type in a base sequence of a nucleic acid according to claim 9 or 10 wherein alteration of the  $H^+$  concentration of either one of said first solution and said second solution is optically measured in said step (c).

**【Claim 11】** The method of discriminating a base type in a base sequence of a nucleic acid according to claim 10 wherein a pH sensitive pigment or a membrane potential sensitive pigment is added to either one of said first solution and said second solution in said step (b).

**【Claim 12】** The method of discriminating a base type in a base sequence of a nucleic acid according to claim 11 wherein acridine orange or Oxonol V is added to either one of said first solution and said second solution in said step (b).

**【Claim 13】** The method of discriminating a base type in a base sequence of a nucleic acid according to claim 9 or 10 wherein alteration of the  $H^+$  concentration of either one of said first solution and said second solution is electrically measured in said step (c).

**【Claim 14】** A device for discriminating a base type which comprises a reaction section in which thermoregulation required for a primer extension reaction is carried out, and a pyrophosphate measurement section in which pyrophosphate is measured, wherein

said pyrophosphate measurement section is characterized by allowing a first solution containing pyrophosphate produced by a primer extension reaction to be reserved in a first region among the first region and a second region provided by comparting with a membrane that retains  $H^+$ -pyrophosphate and hardly permeates  $H^+$  so as to bring said first solution into contact with said  $H^+$ -pyrophosphate, and allowing a second solution to be reserved in said second region; and thereafter measuring alteration of the  $H^+$  concentration of either one of said first solution and said second solution.

**【Claim 15】** The device for discriminating a base type according to claim 14 wherein

said reaction section comprises a slot to which a sample solution introducing chip can be inserted for introducing a sample solution.

**【Claim 16】** The device for discriminating a base type according to claim 14 or 15

which further comprises an analysis means for controlling said reaction section and said pyrophosphate measurement section, and for analyzing the result of the measurement.

**【Claim 17】** A method of detecting a nucleic acid which comprises:

the step (a) of preparing a solution containing a primer which complementarily binds to a nucleic acid having a particular base sequence to prepare a reaction solution by carrying out an extension reaction of said primer;

the step (b) of allowing a first solution prepared from said reaction solution containing pyrophosphate produced when the extension reaction of the primer is caused in said step (a) to be reserved in among a first region and a second region provided by comparting with a membrane that retains  $H^+$ -pyrophosphate and hardly permeates  $H^+$  so as to bring said first solution into contact with said  $H^+$ -pyrophosphate, and allowing a second solution to be reserved in said second region; and

the step (c) of measuring alteration of the  $H^+$  concentration of either one of said first solution and said second solution,

, said method characterized in that an active site that hydrolyzes pyrophosphate of said  $H^+$ -pyrophosphate is exposed to said first region.

**【Claim 18】** The method of detecting a nucleic acid according to claim 17 wherein

said membrane retains another  $H^+$ -pyrophosphate,

the active site that hydrolyzes pyrophosphate of said another  $H^+$ -pyrophosphate is exposed to said second region, and

the concentration of pyrophosphate of said second solution is lower than the concentration of pyrophosphate of said first solution.

**【Claim 19】** The method of detecting a nucleic acid according to claim 17 or 18 wherein

alteration of the  $H^+$  concentration of either one of said first solution and said second solution is optically measured in said step (c).

**【Claim 20】** The method of detecting a nucleic acid according to claim 19 wherein

a pH sensitive pigment or a membrane potential sensitive pigment is added to either one of said first solution and said second solution in said step (b).

**【Claim 21】** The method of a detecting nucleic acid according to claim 20 wherein

acridine orange or Oxonol V is added to either one of said first solution and said second solution in said step (b).

**【Claim 22】** The method of a nucleic acid according to claim 17 or 18 wherein

alteration of the  $H^+$  concentration of either one of said first solution and said second solution is electrically measured in said step (c).

**【Claim 23】** A chip for introducing a sample solution which comprises a reaction chamber for carrying out a primer extension reaction, a pyrophosphate measurement chamber for measuring pyrophosphate, and a flow pass that connects said reaction chamber with said pyrophosphate measurement chamber,

said chip characterized in that said flow pass is constituted to be openable and closable.

**【Claim 24】** The chip for introducing a sample solution according to claim 23 wherein said pyrophosphate measurement chamber comprises

an internal chamber provided in said pyrophosphate measurement chamber;

a  $H^+$  hardly permeable membrane that comparts inside of said pyrophosphate measurement chamber into an internal region and an external region of said internal chamber for reserving a solution;

an electrode that is provided in said internal chamber such that it is brought into contact with a solution reserved in said external region; and

a  $H^+$  sensitive electrode provided such that it is brought into contact with a solution reserved in the internal region of said internal chamber,

said chip characterized in that said membrane retains  $H^+$ -pyrophosphatase such that the active site that hydrolyzes its pyrophosphate is exposed to said external region.

#### **【DETAILED DESCRIPTION OF THE INVENTION】**

##### **【0001】**

##### **【TECHNICAL FIELD WHERE THE INVENTION BELONGS】**

The present invention relates to a method of measuring pyrophosphate, a device for measuring pyrophosphate, a method of detecting nucleic acid, a device for detecting nucleic acid.

##### **【0002】**

##### **【DESCRIPTION OF THE PRIOR ART】**

(First Conventional Technology)

Techniques for determining the presence/absence of a nucleic acid having a particular base sequence are very important techniques. For example, they are essential in diagnoses of hereditary diseases; inspections of food contamination with bacteria, viruses and the like;

and inspections of infection of a human body with bacteria, viruses and the like.

**【0003】**

Hereditary diseases such as severe combined immunodeficiency disease, familial hypercholesterolemia and the like are elucidated to result from deficiency of a particular gene. Hence, the presence/absence of a hereditary disease can be diagnosed by examining the presence/absence of a gene having a particular base sequence which may cause the hereditary disease as described above.

**【0004】**

In recent years, there arises a social problem of food contamination by *Escherichia coli* 0157 and the like. For inspections of food contamination with such bacteria, viruses and the like, the presence/absence of the contamination can be determined by analyzing the presence/absence of a base sequence of a DNA or RNA that is inherent to a bacterium or virus suspected of the contamination. The same applies to inspections of infection of a human body.

**【0005】**

In general, the detection techniques of a base sequence of a particular nucleic acid as described above requires very high sensitivity of detection because the nucleic acid, as a sample, which contains the particular base sequence is included in a slight amount in many cases. At present, the detection techniques that are most commonly used are techniques in which an amplification method of a nucleic acid having a target base sequence is utilized. For example, they include a PCR method, ICAN method, LCR method, SDA method, LAMP method and the like. By way of these amplification methods of a nucleic acid, a nucleic acid having a target base sequence in a sample is amplified in a large quantity, and the nucleic acid having the target nucleic acid is detected. The aforementioned amplification method can readily amplify a nucleic acid having a target base sequence. However, there exist some defects in the method of detecting an amplified nucleic acid having a target base sequence.

**【0006】**

One of the most versatile methods of detecting an amplified nucleic acid having a target base sequence is a method in which the amplified nucleic acid having the target base sequence is separated by electrophoresis, and thereafter a fluorescent intercalating agent such as ethidium bromide or the like is used. Although this method is convenient, on the other hand, special attention must be paid during handling because the fluorescent intercalating agent is a carcinogen.

**【0007】**

Further, other exemplary method may be a dot blot method. In the dot blot method, an amplified double stranded DNA or RNA having a target base sequence is denaturated into a single stranded DNA or RNA by a heat treatment, and fixed onto a membrane such as nylon. Subsequently, it is subjected to radiolelabelling or fluorescent labelling, followed by hybridization to a nucleic acid probe that specifically reacts with the single stranded DNA or RNA described above on the membrane. Finally, detection of the amplified DNA or RNA having the target base sequence is executed by carrying out the detection of the radiolelabelling or fluorescent labelling. However, in this method, time period of 1 to five days is usually consumed when a radiolabelled nucleic acid probe is employed. Further, also in instances where a fluorescent labelled nucleic acid probe is employed, several hours to ten and several hours are also required. In addition, a labelled nucleic acid probe must be prepared for each amplified nucleic acid having the target base sequence, and a burden has been thereby imposed.

#### 【0008】

The PCR method is a technique in which a nucleic acid having a target base sequence is amplified while repeating a DNA extension reaction from a primer, with the use of DNA polymerase, in general (hereinafter, referred to as primer extension reaction). Application of use of the primer extension reaction is not limited to the detection of a nucleic acid having a target base sequence.

#### 【0009】

Recently, it has been elucidated that polymorphism of just one base pair in a base sequence, what is called SNP (Single Nucleotide Polymorphism: polymorphism of a single base), affects susceptibility to a disease such as diabetes, hypertension or the like, efficacy of a drug, or the like. Therefore, great importance has been put on a SNP typing technique in which a SNP pattern of each individual is analyzed. Moreover, cases in which a substitution of only one base pair in a base sequence within a genomic DNA becomes the cause of a serious disease have been known. Accordingly, analyses of the presence/absence of such a substitution of a single base pair have also become of great importance. The SNP typing technique is also effective in the discrimination of the presence/absence of such a substitution of a single base pair.

#### 【0010】

Currently, a variety of SNP typing techniques have been developed or already put into practice. In one of the most convenient techniques among those techniques, a primer extension reaction has

been utilized. In this technique, SNP typing is executed by determining whether or not a primer extension reaction is caused.

**【0011】**

For the present, discrimination techniques of the base type of a SNP site in which a primer extension reaction is utilized can be generally classified into two groups. One includes primer extension reaction-utilizing methods where 4 kinds of dNTPs (dATP, dCTP, dGTP, dTTP) are used. Another includes primer extension reaction-utilizing methods where one kind of dNTP or ddNTP alone is used.

**【0012】**

The primer extension reaction-utilizing method where 4 kinds of dNTPs are used is explained with reference to Fig. 19 and Fig. 20. In this method, a primer that has a complementary base sequence to the base sequence that is adjacent to the SNP site of a target DNA, and that results in a difference of progress of the extension reactions depending on the base type of the SNP site of the target DNA (hereinafter, referred to as typing primer) is used. Specifically, the steps explained below are carried out.

**【0013】**

First, in the step illustrated in Fig. 19 (a), a sample solution containing a target DNA 1 having a SNP site S1 is prepared. Similarly, in the step illustrated in Fig. 20 (a), a sample solution containing a target DNA 2 having a SNP site S2 is prepared.

**【0014】**

Next, in the step illustrated in Fig. 19 (b), the DNA 1 is converted to single stranded DNAs 3 and 4 by thermal denaturation or the like. Similarly, in the step illustrated in Fig. 20 (b), the DNA 2 is converted to single stranded DNAs 5 and 6 by thermal denaturation or the like.

**【0015】**

Next, in the step illustrated in Fig. 19 (c), to the sample solution containing the single stranded DNAs 3 and 4, are added a typing primer 7, DNA polymerase 8 and 4 kinds of dNTPs. Similarly, in the step illustrated in Fig. 20 (c), to the sample solution containing the single stranded DNAs 5 and 6, are added a typing primer 7, DNA polymerase 8 and 4 kinds of dNTPs. The typing primer 7 herein is designed such that it completely hybridizes to the 3' end sided region from the SNP site of the single stranded DNAs 4 and 6, except for the base at its 3' end (in this case, thymine (hereinafter, denoted as T)).

**【0016】**

Next, in the step illustrated in Fig. 19 (d), the typing primer 7 completely hybridizes to the single stranded DNA 4 having the SNP site S1 of adenine (hereinafter, denoted as A). Thus, a primer extension reaction is caused, thereby consuming dNTP by the DNA polymerase 8.

**【0017】**

On the other hand, in the step illustrated in Fig. 20 (d), only the base at the 3' end of the typing primer 7 (T) can not hybridize to the single stranded DNA 6 having the SNP site S2 of guanine (hereinafter, denoted as G). Hence, a normal primer extension reaction hardly occurs. Therefore, dNTP is hardly consumed.

**【0018】**

Accordingly, discrimination of a base at the SNP site is permitted by analyzing the difference of progress of these extension reactions. In such a manner, discrimination of the base at a SNP site is executed on the basis that a primer extension reaction occurs or not. In this method, similar analysis can be effected also in cases where the base at the SNP site can be of 3 types or 4 types, when typing primers corresponding respectively thereto are provided.

**【0019】**

In regard to the typing primer, ones other than the primer having the 3' end base to match to the base of the SNP site of the DNA, as described above, have been also developed. For example, ASP (Allele Specific Primer) developed by Toyobo Co., Ltd. is included (see, nonpatent literature 1). ASP is a primer designed such that it has the second base from its 3' end corresponding to the SNP site, and in addition, the third base from its 3' end being certainly noncomplementary to the target base.

**【0020】**

**【Nonpatent literature 1】**

Web site of Toyobo Co., Ltd., retrieved on October 1, 2002, URL (<http://www.toyobo.co.jp/seihin/xr/product/custom/snps/snps.html>)

**【0021】**

It is reported that by using ASP together with  $\alpha$  type DNA polymerase having potent calibrating activity, more accurate discrimination of the base type of a SNP site than the methods illustrated in Fig. 19 and Fig. 20 as described above is enabled. More specifically, when the SNP site is complementary to the second base from the 3' end of ASP, a favorable extension reaction is caused, but when it is not complementary thereto, the extension reaction is not properly caused. Furthermore, the difference of progress of the extension reactions between the cases with and without the occurrence

of the extension reaction has been reported to be greater than the methods illustrated in Fig. 19 and Fig. 20 as described above.

#### 【0022】

Next, the primer extension reaction-utilizing method where 1 kind of dNTP (or ddNTP) is used is explained with reference to Fig. 21 and Fig. 22. In this method, the extension reaction is performed using a primer designed such that it hybridizes to a region that is adjacent to the SNP site in a target single stranded DNA. In other words, a site that corresponds to the SNP site is not present in the primer sequence. Specifically, the steps explained below are carried out.

#### 【0023】

First, in the step illustrated in Fig. 21 (a), a sample solution containing a target DNA 1 having a SNP site S1 is prepared. Similarly, in the step illustrated in Fig. 22 (a), a sample solution containing a target DNA 2 having a SNP site S2 is prepared.

#### 【0024】

Next, in the step illustrated in Fig. 21 (b), the DNA 1 is converted to single stranded DNAs 3 and 4 by thermal denaturation or the like. Similarly, in the step illustrated in Fig. 22 (b), the DNA 2 is converted to single stranded DNAs 5 and 6 by thermal denaturation or the like.

#### 【0025】

Next, in the step illustrated in Fig. 21 (c), to the sample solution containing the single stranded DNAs 3 and 4, are added a primer 9, DNA polymerase 8 and dCTP (or ddCTP). Similarly, in the step illustrated in Fig. 22 (c), to the sample solution containing the single stranded DNAs 5 and 6, are added a primer 9, DNA polymerase 8 and dCTP (or ddCTP). The primer 9 herein is designed such that it completely hybridizes to a region that is adjacent to the 3' end side from the SNP site of the single stranded DNAs 4 and 6.

#### 【0026】

Next, in the step illustrated in Fig. 21 (d), the primer 9 completely hybridizes to the single stranded DNA 4. However, a primer extension reaction is not caused because the SNP site S1 of the single stranded DNA 4 is A, and only dCTP (or ddCTP) is supplied. Thus, dCTP (or ddCTP) is hardly consumed by the DNA polymerase 8.

#### 【0027】

On the other hand, in the step illustrated in Fig. 22 (d), the primer 9 completely hybridizes to the single stranded DNA 6. Upon this step, a normal primer extension reaction is caused through the supply of dCTP (or ddCTP) because the SNP site S2 in the single stranded DNA

6 is G. Accordingly, dCTP (or ddCTP) is consumed by the DNA polymerase 8.

**【0028】**

In cases where the base at the SNP site can be of 3 types or 4 types, similar analyses are allowed by using dNTP or ddNTP that corresponds thereto, respectively.

**【0029】**

Thus, in the method in which one kind dNTP or ddNTP alone, differently from the method in which all 4 kinds of dNTPs described above are used, only approximately one to several bases are generally added to the primer when dNTP is used, whilst only one base is added to the primer when ddNTP is used. Therefore, it is quite difficult to detect the difference of progress of the extension reactions. Then, in patent literatures 1 and 2, a method is employed in which pyrophosphate that is produced during the progress of the primer extension reaction is converted to ATP, and the amount of pyrophosphate is thereafter measured utilizing a luciferase reaction, for the purpose of detecting the difference of progress of the extension reactions. Advantages of the method in which one kind of dNTP alone is used include the aspect that discrimination is enabled of not only the SNP site but also the base sequence in the vicinity of the SNP site, by repeating the steps according to each step illustrated in Fig. 21 or Fig. 22, depending on how the primer is designed.

**【0030】**

**【Patent literature 1】**

JP-A No. 2001-506864 (A section of Summary)

**【Patent literature 2】**

JP-A No. 2001-501092 (A section of Summary)

**【0031】**

As described hereinabove, there have existed several kinds of discrimination techniques of the base type of a SNP site in which a primer extension reaction is utilized, however, in any one of the discrimination techniques of the base type of a SNP site, the aspect that discrimination of the base type of a SNP site is effected by analyzing the difference of progress of the primer extension reactions is common.

**【0032】**

Such discrimination techniques of the base type of a SNP site are extremely useful techniques which can be applied to the discrimination of not alone so called SNP site, but of a desired particular base. It is highly possible that they are utilized

routinely at a variety of hospitals irrespective of either large or small scale, in the near future. Therefore, methods which allow for the analysis of a difference of primer extension reactions in safer and more accurate manner have been needed.

**【0033】**

**(Second Conventional Technology)**

Pyrophosphate has been known to greatly participate in enzyme reactions in cells. For example, in a process of synthesis of a protein, pyrophosphate is produced during a reaction in which an amino acid forms an aminoacyl tRNA via aminoacyl adenylate. Further, in a process of synthesis of starch found in e.g., plants and the like, pyrophosphate is produced when ADP-glucose is produced by the reaction between glucose-1-phosphate and ATP. Apart from them, it has been known that pyrophosphate participates in various enzyme reactions. Therefore, techniques for quantitatively determining pyrophosphate are important techniques upon analyses of cellular states, enzyme reactions as described above, or the like.

**【0034】**

A chemical method developed by Grindley et al. (see nonpatent literature 2) has been known as conventional method for the measuring of pyrophosphate. However, this method is accompanied by high risk because it requires concentrated sulfuric acid.

**【0035】**

**【Nonpatent literature 2】**

G.B.Grindley and C.A.Nichel, Anal.Biochem,.vol33.p114(1970)

**【Patent literature 3】**

JP-A No. 61-12300

**【0036】**

In patent literature 3, three kinds of methods of measuring pyrophosphate in which an enzyme is utilized and risky chemicals such as concentrated sulfuric acid are not used are disclosed. Those are explained below.

**【0037】**

In the first method, pyrophosphate is brought into the action of pyruvate orthophosphate dikinase in the presence of phosphoenol pyruvate and adenosine monophosphate. Because pyruvic acid is produced by this reaction, the amount of pyrophosphate can be derived by calculation through measuring the amount of the pyruvic acid. As methods of measuring the amount of pyruvic acid, two kinds of methods have been proposed. One is a method in which decrease of NADH is colorimetrically determined upon reduction of pyruvic acid with NADH utilizing a catalytic action of lactate dehydrogenase. In another

method, hydrogen peroxide, which is produced by bringing thus produced pyruvic acid into the action of pyruvate oxidase, is introduced to a pigment to allow for a colorimetric determination.

**【0038】**

In the second method, pyrophosphate is brought into the action of glycerol-3-phosphate cytidyl transferase in the presence of cytidine diphosphorus glycerol. Glycerol triphosphate is produced by this reaction. Therefore, the amount of pyrophosphate can be derived by calculation through measuring the amount of thus produced glycerol triphosphate. As methods of measuring the amount of glycerol triphosphate, two kinds of methods have been proposed. One is a method in which increase of NAD(P)H is colorimetrically determined upon oxidation of glycerol triphosphate with NAD(P) utilizing a catalytic action of glycerol-3-phosphate dehydrogenase. In another method, hydrogen peroxide, which is produced by bringing thus produced glycerol triphosphate into the action of glycerol-3-phosphate oxidase, is introduced to a pigment to allow for a colorimetric determination. Another is a method in which colorimetric determination is carried out through introducing hydrogen peroxide, which is produced by bringing thus produced, to a pigment.

**【0039】**

In the third method, pyrophosphate is brought into the action of ribitol-5-phosphate cytidyl transferase in the presence of cytidine diphosphate ribitol. Because D-ribitol-5-phosphate is produced by this reaction, the amount of pyrophosphate can be determined through measuring its amount produced accordingly. As a method of measuring the amount of D-ribitol-5-phosphate, a method in which increase of NADH (or NADPH) is colorimetrically determined through bringing it into the action of ribitol-5-phosphate dehydrogenase in the presence of NAD (or NADP).

**【0040】**

**【PROBLEMS TO BE SOLVED BY THE INVENTION】**

As is described in above the first conventional technology, there are several kinds of discrimination techniques of the base type of a SNP site in which a primer extension reaction is utilized. In any one of discrimination techniques of the base type of a SNP site, it is common in respect that discrimination of the base type of a SNP site is executed by analyzing the difference of progress of the primer extension reactions.

**【0041】**

There are two kinds of methods of analyzing the difference of primer extension reactions. One involves techniques in which an

amplification method of a target base sequence such as PCR method, ICAN method, LCR method, SDA method, LAMP method or the like, and a technique for detecting a nucleic acid are utilized. In other words, amplification of a base sequence including a SNP site is carried out using the aforementioned typing primer as one primer. As a result, when the base at its 3' end of the typing primer is complementary to a SNP site which is an object to be analyzed, a nucleic acid having a target base sequence can be well amplified, however, when it is not complementary thereto, the nucleic acid is hardly amplified. Therefore, by measuring the amount of the objective base sequence fragment with use of a labelling substance such as a fluorescent intercalating agent or the like, discrimination of the base type of a SNP site can be performed. However, as already stated, it is disadvantageous in the need of a very dangerous operation because the fluorescent intercalating agent is a carcinogen.

#### **【O O 4 2】**

Another method is measuring pyrophosphate that is produced with extension of the primer. For example, pyrophosphate is converted to ATP, and thereafter a luciferase reaction is utilized. However, when dATP is used in a primer extension reaction, dATP becomes a substrate for the luciferase reaction similarly to ATP. Thus, accurate discrimination of the base type of a SNP site can not be achieved. Therefore, it is disadvantageous in that a special dATP analogue must be used which acts as a substrate for DNA polymerase instead of dATP, and does not act as a substrate for a luciferase reaction.

#### **【O O 4 3】**

In addition, as described in the aforementioned second conventional technology, there exist disadvantages also in other technique for measuring pyrophosphate, in aspects that multiple kinds of enzymes, reagents and the like are needed, the cost is elevated, and the steps are complicated.

#### **【O O 4 4】**

The present invention was accomplished in order to solve the disadvantages as described hereinabove, and provides convenient technique for measuring pyrophosphate, technique for detecting target nucleic acid, and technique for discriminating base type of base sequence of target nucleic acid.

#### **【O O 4 5】**

#### **【MEANS FOR SOLVING THE PROBLEM】**

The present invention is directed to a method of measuring pyrophosphate which comprises a step (a) of allowing a first solution containing pyrophosphate to be reserved in a first region among the

first region and a second region provided by comparting with a membrane that retains  $H^+$ -pyrophosphate and hardly permeates  $H^+$  so as to bring the first solution into contact with the  $H^+$ -pyrophosphate, and allowing a second solution to be reserved in the second region; and a step (b) of measuring alteration of the  $H^+$  concentration of either one of the first solution and the second solution, the method characterized in that an active site that hydrolyzes pyrophosphate of the  $H^+$ -pyrophosphate is exposed to the first region.

【0046】

In natural world,  $H^+$ -pyrophosphatase is retained in a tonoplast membrane such that the active site thereof which hydrolyzes pyrophosphate is exposed to outside of the tonoplast membrane, and it has a property to transport  $H^+$  from outside of the tonoplast membranes toward inside of the tonoplast membranes accompanied by a hydrolysis reaction in which two molecules of phosphoric acid are formed from one molecule of pyrophosphate. Hence, the  $H^+$  concentration is increased within the tonoplast membrane due to the enzyme reaction of  $H^+$ -pyrophosphatase, while the  $H^+$  concentration is decreased outside of the tonoplast membrane. According to the present invention, through reserving a sample solution, which is going to include pyrophosphate when an extension reaction proceeds, in a first region where an active site of  $H^+$ -pyrophosphatase that hydrolyzes pyrophosphate is exposed,  $H^+$  is transported from the first region to a second region when the extension reaction proceeds, and thus the  $H^+$  concentrations at the front face side and the back face side of the tonoplast membrane vary. Consequently, the amount of pyrophosphate in the sample solution can be detected by measuring the  $H^+$  concentration at either one of the front face side or the back face side. Therefore, according to the method of the present invention in which the base type in a base sequence of a nucleic acid is discriminated by measuring pyrophosphate produced by the extension reaction of the primer, multiple kinds of enzymes, reagents and the like for measuring pyrophosphate are not required, with simple steps, leading to reduction of the cost.

【0047】

The structure can be as follows. The aforementioned membrane retains another  $H^+$ -pyrophosphate, and the active site that hydrolyzes pyrophosphate of the another  $H^+$ -pyrophosphate is exposed to the second region, the concentration of pyrophosphate of the second solution is lower than the concentration of pyrophosphate of the first solution.

【0048】

Alteration of the  $H^+$  concentration of either one of the first solution and the second solution can be optically measured in the step (b).

**【0049】**

A pH sensitive pigment or a membrane potential sensitive pigment can be added to either one of the first solution and the second solution in the step (a).

**【0050】**

Acridine orange or Oxonol V is preferably added to either one of the first solution and the second solution in the step (a).

**【0051】**

Acridine orange is extremely sensitive pigments on a slight change of pH, and Oxonol V is extremely sensitive pigments on a slight change of membrane potential. Accordingly, measuring of pyrophosphate with high sensitivity is enabled with the addition of each pigment.

**【0052】**

Alteration of the  $H^+$  concentration of either one of the first solution and the second solution can be electrically measured in a step (b).

**【0053】**

The present invention is directed to a device for measuring pyrophosphate which comprises a vessel, an internal chamber provided in the vessel, a  $H^+$  hardly permeable membrane that comparts inside of the vessel into an internal region and an external region of the internal chamber for reserving a solution, an electrode that is provided such that it is brought into contact with a solution reserved in the external region of the internal chamber, and a  $H^+$  sensitive electrode provided such that it is brought into contact with a solution reserved in the internal region of the internal chamber, the device characterized in that the membrane retains  $H^+$ -pyrophosphatase such that the active site that hydrolyzes its pyrophosphate is exposed to the external region.

**【0054】**

When a sample solution is injected into the pyrophosphate detection chamber, an enzyme reaction of  $H^+$ -pyrophosphatase is caused when pyrophosphate is present in the sample solution, thereby leading to increase of the  $H^+$  concentration in the internal region of the internal chamber which is separated by the membrane, and to decrease of the  $H^+$  concentration in the external region of the internal chamber. Accordingly, the  $H^+$  concentration can be electrically measured with an electrode and a  $H^+$  sensitive electrode, thereby enabling the measuring of the amount of pyrophosphate.

#### 【0055】

The present invention is directed to a method of discriminating a base type in a base sequence of a nucleic acid which comprises the step (a) of preparing a solution containing a nucleic acid, and a primer having a base sequence that includes a complementary binding region which complementarily binds to the nucleic acid to prepare a reaction solution by carrying out an extension reaction of the primer, the step (b) of allowing a first solution prepared from the reaction solution containing pyrophosphate produced when the extension reaction of the primer is caused in the step (a) to be reserved in among a first region and a second region provided by comparting with a membrane that retains  $H^+$ -pyrophosphate and hardly permeates  $H^+$  so as to bring the first solution into contact with the  $H^+$ -pyrophosphate, and allowing a second solution to be reserved in the second region, and the step (c) of measuring alteration of the  $H^+$  concentration of either one of the first solution and the second solution, the method characterized in that an active site that hydrolyzes pyrophosphate of the  $H^+$ -pyrophosphate is exposed to the first region.

#### 【0056】

As a method of discriminating the base type of a particular base there exists a, for example, method in which the base type of a base to which the discrimination is intended is discriminated on the basis of the extent of progress of a primer extension reaction, when the primer extension reaction is carried out using a primer having a completely complementary sequence to the base sequence adjacent to the 3' end side from the base to which the discrimination is intended, and dNTP which is complementary to the predicted base type of the base to which the discrimination is intended. Further, there also exists a method in which a primer is used which has a complementary base sequence to a base sequence including a base to which the discrimination is intended, and which causes a difference of the extent of the progress of a primer extension reaction depending on the base type of a base to which the discrimination is intended when the primer extension reaction is carried out using 4 kinds of dNTPs simultaneously. In any of these methods, it is common in respect that discrimination of the base type of a particular base is carried out on the basis of the extent of the progress of the primer extension reactions. When a primer extension reaction is caused, pyrophosphate is produced. According to the present invention, the extent of the progress of the primer extension reactions can be analyzed through measuring pyrophosphate produced by primer extension reactions.

Therefore, discrimination of the base type of a particular base is permitted.

**【0057】**

The structure can be as follows. The membrane retains another  $H^+$ -pyrophosphate, the active site that hydrolyzes pyrophosphate of the another  $H^+$ -pyrophosphate is exposed to the second region, and the concentration of pyrophosphate of the second solution is lower than the concentration of pyrophosphate of the first solution.

**【0058】**

Alteration of the  $H^+$  concentration of either one of the first solution and the second solution can be optically measured in the step (c).

**【0059】**

A pH sensitive pigment or a membrane potential sensitive pigment can be added to either one of the first solution and the second solution in the step (b).

**【0060】**

Acridine orange or Oxonol V is preferably added to either one of the first solution and the second solution in the step (b).

**【0061】**

Alteration of the  $H^+$  concentration of either one of the first solution and the second solution can be electrically measured in the step (c).

**【0062】**

The present invention is directed to a device for discriminating a base type which comprises a reaction section in which thermoregulation required for a primer extension reaction is carried out, and a pyrophosphate measurement section in which pyrophosphate is measured, wherein the pyrophosphate measurement section is characterized by allowing a first solution containing pyrophosphate produced by a primer extension reaction to be reserved in a first region among the first region and a second region provided by comparting with a membrane that retains  $H^+$ -pyrophosphate and hardly permeates  $H^+$  so as to bring the first solution into contact with the  $H^+$ -pyrophosphate, and allowing a second solution to be reserved in the second region, and thereafter measuring alteration of the  $H^+$  concentration of either one of the first solution and the second solution.

**【0063】**

As a method of discriminating the base type of a particular base there exists a, for example, method in which the base type of a base to which the discrimination is intended is discriminated on the

basis of the extent of progress of a primer extension reaction, when the primer extension reaction is carried out using a primer having a completely complementary sequence to the base sequence adjacent to the 3' end side from the base to which the discrimination is intended, and dNTP which is complementary to the predicted base type of the base to which the discrimination is intended. Further, there also exists a method in which a primer is used which has a complementary base sequence to a base sequence including a base to which the discrimination is intended, and which causes a difference of the extent of the progress of a primer extension reaction depending on the base type of a base to which the discrimination is intended when the primer extension reaction is carried out using 4 kinds of dNTPs simultaneously. In any of these methods, it is common in respect that discrimination of the base type of a particular base is carried out on the basis of the extent of the progress of the primer extension reactions. When a primer extension reaction is caused, pyrophosphate is produced. According to the device for discriminating a base type of the present invention, the extent of the progress of the primer extension reactions can be analyzed through measuring pyrophosphate produced by a primer extension reaction. Therefore, discrimination of the base type of a particular base is permitted.

#### **【0064】**

Moreover, when discrimination of the presence/absence of a nucleic acid having a particular base sequence in a sample solution is intended, presence of a nucleic acid having a base sequence that is complementary to the primer in the solution is revealed, when the primer extension reaction proceeds. To the contrary, absence of a nucleic acid having a base sequence that is complementary to the primer in the solution is revealed, when the primer extension reaction does not proceed so much. Thus, using the device for discriminating a base type of the present invention, discrimination of the presence/absence of a nucleic acid having a particular base sequence in a sample solution, i.e., detection of a particular nucleic acid is also enabled.

#### **【0065】**

The reaction section can comprise a slot to which a sample solution introducing chip can be inserted for introducing a sample solution.

#### **【0066】**

The device for discriminating a base type can further comprises an analysis means for controlling the reaction section and

the pyrophosphate measurement section, and for analyzing the result of the measurement.

**【0067】**

The present invention is directed to a method of detecting a nucleic acid which comprises the step (a) of preparing a solution containing a primer which complementarily binds to a nucleic acid having a particular base sequence to prepare a reaction solution by carrying out an extension reaction of the primer, the step (b) of allowing a first solution prepared from the reaction solution containing pyrophosphate produced when the extension reaction of the primer is caused in the step (a) to be reserved in among a first region and a second region provided by comparting with a membrane that retains  $H^+$ -pyrophosphate and hardly permeates  $H^+$  so as to bring the first solution into contact with the  $H^+$ -pyrophosphate, and allowing a second solution to be reserved in the second region, and the step (c) of measuring alteration of the  $H^+$  concentration of either one of the first solution and the second solution, the method characterized in that an active site that hydrolyzes pyrophosphate of the  $H^+$ -pyrophosphate is exposed to the first region.

**【0068】**

A primer hybridizes to a nucleic acid having a complementary base sequence, and is extended by a primer extension reaction. When a primer extension reaction is caused, pyrophosphate is produced. According to the present invention, the extent of progress of the primer extension reaction can be analyzed by detecting the amount of pyrophosphate, more specifically, by measuring the  $H^+$  concentration. When the primer extension reaction proceeded, it is revealed that a nucleic acid having a base sequence that is complementary to the primer is present in the first solution. To the contrary, when the primer extension reaction did not proceed so much, it is revealed that a nucleic acid having a base sequence that is complementary to the primer is almost absent in the first solution. In such a manner, the presence/absence of a nucleic acid having a particular base sequence in the first solution can be discriminated, i.e., detection of a particular nucleic acid is enabled.

**【0069】**

The structure can be as follows. The membrane retains another  $H^+$ -pyrophosphate, the active site that hydrolyzes pyrophosphate of the another  $H^+$ -pyrophosphate is exposed to the second region, and the concentration of pyrophosphate of the second solution is lower than the concentration of pyrophosphate of the first solution.

**【0070】**

Alteration of the  $H^+$  concentration of either one of the first solution and the second solution can be optically measured in the step (c).

**【0071】**

A pH sensitive pigment or a membrane potential sensitive pigment can be added to either one of the first solution and the second solution in the step (b).

**【0072】**

Acridine orange or Oxonol V is preferably added to either one of the first solution and the second solution in the step (b).

**【0073】**

Alteration of the  $H^+$  concentration of either one of the first solution and the second solution is electrically measured in the step (c).

**【0074】**

The present invention is directed to a chip for introducing a sample solution which comprises a reaction chamber for carrying out a primer extension reaction, a pyrophosphate measurement chamber for measuring pyrophosphate, and a flow pass that connects the reaction chamber with the pyrophosphate measurement chamber, the chip characterized in that the flow pass is constituted to be openable and closable.

**【0075】**

According to the tip for introducing a sample solution according to the present invention, the reaction chamber and the pyrophosphate detection chamber can be sealed off individually because the aforementioned flow pass is constituted such that it can be opened and closed. Therefore, the primer extension reaction and detection of pyrophosphate of which reaction temperature conditions are different with each other can be executed on one tip.

**【0076】**

The aforementioned pyrophosphate measurement chamber preferably comprises an internal chamber provided in the pyrophosphate measurement chamber, a  $H^+$  hardly permeable membrane that comparts inside of the pyrophosphate measurement chamber into an internal region and an external region of the internal chamber for reserving a solution, an electrode that is provided in the internal chamber such that it is brought into contact with a solution reserved in the external region, and a  $H^+$  sensitive electrode provided such that it is brought into contact with a solution reserved in the internal region of the internal chamber, the chip characterized in that the membrane

retains H<sup>+</sup>-pyrophosphatase such that the active site that hydrolyzes its pyrophosphate is exposed to the external region.

【0077】

When a sample solution is injected into the pyrophosphate detection chamber, an enzyme reaction of H<sup>+</sup>-pyrophosphatase is caused when pyrophosphate is present in the sample solution, thereby leading to increase of the H<sup>+</sup> concentration in the internal region of the internal chamber which is separated by the membrane, and to decrease of the H<sup>+</sup> concentration in the external region of the internal chamber. Accordingly, the H<sup>+</sup> concentration can be electrically measured with an electrode and a H<sup>+</sup> sensitive electrode, thereby enabling the detection of the amount of pyrophosphate.

【0078】

#### 【EMBODIMENT OF THE INVENTION】

Embodiments of the present invention are explained below with reference to the drawings. Nucleic acids such as DNA and RNA described herein are double stranded unless specifically indicated.

【0079】

(Embodiment 1)

In this Embodiment, a method of discriminating the base type of a SNP site of a target DNA in a sample is explained. Specifically, methods in which a primer extension reaction (for example, an amplification reaction such as PCR method, ICAN method, LCR method, SDA method, LAMP method or the like) is utilized using 4 kinds of dNTPs is explained with reference to Fig. 1 and Fig. 2. Fig. 1 and Fig. 2 are process drawings showing the method of discriminating the base type of a SNP site of a target DNA in a sample according to this Embodiment.

【0080】

In the method of this Embodiment, a primer is used which has a complementary base sequence to a base sequence adjacent to a SNP site of a target DNA, and causes the difference of progress of the extension reaction depending on the base type of the SNP site of the target DNA (hereinafter, referred to as a typing primer). In this Embodiment, an example is demonstrated in which there exists a possibility that the base of a SNP site in a single stranded target DNA on which a typing primer acts is A or G, and the typing primer for use is designed such that the primer extension reaction is not caused when the base is G, but is caused when the base is A.

【0081】

First, in the step illustrated in Fig. 1 (a), a sample solution containing a target DNA 1 having a SNP site S1, a typing primer 7, DNA

polymerase 8 and 4 kinds of dNTPs is prepared. Similarly, in the step illustrated in Fig. 2 (a), a sample solution containing a target DNA 2 having a SNP site S2, a typing primer 7, DNA polymerase 8 and 4 kinds of dNTPs. The typing primer 7 herein is designed such that it completely hybridizes to the 3' end sided region from the SNP site of single stranded DNAs 4 and 6, except for its base at 3' end (in this case, thymine (hereinafter, denoted as T)). Moreover, the DNA polymerase 8 used in this Embodiment is a known enzyme having heat resistance, which is generally used in PCR and the like.

**【0082】**

Next, in the step illustrated in Fig. 1 (b), the sample solution is heated to subject the DNA 1 to thermal denaturation to give single stranded DNAs 3 and 4. Similarly, in the step illustrated in Fig. 2 (b), the sample solution is heated to subject the DNA 2 to thermal denaturation to give single stranded DNAs 5 and 6.

**【0083】**

Next in the step illustrated in Fig. 1 (c), the sample solution is cooled to allow hybridization of the single stranded DNAs 3 and 4 to the typing primer 7. Similarly, in the step illustrated in Fig. 2 (c), the sample solution is cooled to allow hybridization of the single stranded DNAs 5 and 6 to the typing primer 7.

**【0084】**

Next, in the step illustrated in Fig. 1 (d), the temperature of the sample solution is regulated to an optimal temperature for the primer extension reaction. The typing primer 7 has completely hybridized to the single stranded DNA 4 of which SNP site is adenine (hereinafter, denoted as A). Thus, the primer extension reaction is caused, and dNTP is consumed by the DNA polymerase 8 to produce pyrophosphate.

**【0085】**

On the other hand, also in the step illustrated in Fig. 2 (d), the temperature of the sample solution is regulated to an optimal temperature for the primer extension reaction. However, the typing primer 7 has been in a state where its 3' end base (T) does not hybridize to the single stranded DNA 6 of which SNP site S2 is guanine (hereinafter, denoted as G). Thus, normal primer extension reaction hardly occurs. Therefore, dNTP is hardly consumed, and thus pyrophosphate is hardly produced.

**【0086】**

Subsequently, by repeating the steps illustrated in Fig. 1 (b) to (d), and the steps illustrated in Fig. 2 (b) to (d) as described above, the primer extension reaction is repeated. Accordingly, the

difference of progress of the primer extension reactions illustrated in Fig. 1 (d) and Fig. 2 (d) is remarkably exhibited.

**【0087】**

Instead of the method of this Embodiment, a PCR reaction may be carried out using the typing primer 7 as one of two primers used in the PCR reaction, together with use of another primer. The difference of progress of the primer extension reactions is thereby expanded exponentially. In addition, other amplification reaction except for the PCR method can be also applied.

**【0088】**

Finally, the difference of progress of the primer extension reactions illustrated in Fig. 1 (d) and Fig. 2 (d) is analyzed by quantitative detection of pyrophosphate. Accordingly, the discrimination of the base type of a SNP site is enabled. Next, the method of quantitatively detecting pyrophosphate of this Embodiment is explained with reference to Fig. 3.

**【0089】**

In this Embodiment,  $H^+$ -pyrophosphatase is used for measuring pyrophosphate. Fig. 3 is a drawing schematically showing  $H^+$ -pyrophosphatase.

**【0090】**

As is shown in Fig. 3,  $H^+$ -pyrophosphatase is a membrane protein that generally exists in tonoplast membranes and the like of a plant, and  $H^+$ -pyrophosphatase 11 has a property to transport  $H^+$  from the outside of the tonoplast membrane 13 that does not pass or hardly passes  $H^+$ , toward the inside of the tonoplast membrane, accompanied by a hydrolysis reaction that produces two molecules of phosphoric acid 12 from one molecule of pyrophosphate 10. Thus, by the enzyme reaction of  $H^+$ -pyrophosphatase, the  $H^+$  concentration is increased within the tonoplast membrane, while the  $H^+$  concentration is decreased outside of the tonoplast membrane.

**【0091】**

Therefore, in this Embodiment, a sample solution containing pyrophosphate is brought into contact with  $H^+$ -pyrophosphatase in a state indwelling in a tonoplast membrane which had been isolated from a plant or the like. Thereafter, the change of the  $H^+$  concentration of either inside of the tonoplast membrane or outside of the tonoplast membrane is measured. Thus, the amount of pyrophosphate in the sample solution is measured, and then the difference in progress of the extension reactions of a primer shown in Fig. 1 (d) and Fig. 2 (d) is analyzed. The base type of a SNP site in a sample solution is

discriminated by the analysis of the difference in progress of the extension reaction of a primer.

**【0092】**

Exemplary method for measuring the change of the  $H^+$  concentration includes the method in which the change of the  $H^+$  concentration is measured after converting it into an optical change, and the method of electrical measurement. Examples of the method in which the change of the  $H^+$  concentration is measured after converting it into an optical change include methods in which a pH test paper, a pH sensitive pigment, a membrane potential sensitive pigment or the like is used. Examples of the method of electrical measurement include metal electrode methods (hydrogen electrode method, quinhydrone electrode method, antimony electrode method and the like), glass electrode methods, ISFET electrode methods, patch clamp methods, LAPS (Light-Addressable Potentiometric Sensor) methods and the like.

**【0093】**

By using the aforementioned method of measuring the change of the  $H^+$  concentration, and the aforementioned reaction of  $H^+$ -pyrophosphatase in combination, pyrophosphate in a sample solution can be measured after converting it into an optical signal or an electrical signal.

**【0094】**

The method of measuring the change of the  $H^+$  concentration is not limited to the method of the measurement as described above, but may be any method capable of converting the change of the  $H^+$  concentration into an optical change or an electrical change, and capable of sensing the optical change or the electrical change.

**【0095】**

Next, the method of measuring pyrophosphate of this Embodiment is explained with reference to Fig. 4 and Fig. 5. Fig. 4 and Fig. 5 are drawings showing a method of measuring pyrophosphate.

**【0096】**

As is shown in Fig. 4, a solution of suspended membrane vesicles 33 having  $H^+$ -pyrophosphatase indwelled in the membrane, and including a pH sensitive pigment or a membrane potential sensitive pigment therein is poured into a reaction vessel 31. Then, into the reaction vessel 31 is added a sample solution 32 obtained in Fig. 1 (d) or Fig. 2 (d). Upon this operation, the active site of  $H^+$ -pyrophosphatase that hydrolyzes pyrophosphate is exposed to outside of the membrane vesicle 33.

**【0097】**

When pyrophosphate is present in the sample solution 32, an enzyme reaction of  $H^+$ -pyrophosphatase is caused. Thus, the  $H^+$  concentration is increased inside of the membrane vesicle 33, while the  $H^+$  concentration is decreased outside of the membrane vesicle 33. Consequently, increase of the  $H^+$  concentration inside of the membrane vesicle 33 alters fluorescence intensity of the pH sensitive pigment or the membrane potential sensitive pigment. By optically measuring the change of this fluorescence intensity, measuring of pyrophosphate can be effected.

#### 【0098】

The membrane vesicle 33 which may be used is that prepared from vacuole isolated from cells. Further, as the membrane vesicle 33, any of those formed by isolating and purifying  $H^+$ -pyrophosphatase, followed by reconstituting it within a membrane such as artificially formed lipid bilayer membrane, LB membrane or the like, which is not or hardly  $H^+$  permeable, such that the enzyme is indwelled therein may be used.

#### 【0099】

$H^+$ -pyrophosphatase of which active site that hydrolyzes pyrophosphate is exposed inside may be included in the membrane vesicle 33. However, when a membrane vesicle 33 including  $H^+$ -pyrophosphatase of which active site that hydrolyzes pyrophosphate is exposed inside is used, it is preferred that the concentration of pyrophosphate inside of the membrane vesicle 33 is set to be lower than the concentration of pyrophosphate outside of the membrane vesicle. Most preferably, pyrophosphate is not included inside of the membrane vesicle 33. Thus, the transport of  $H^+$  from inside to outside of the membrane vesicle 33 decreases or arrests, thereby dominating the transport of  $H^+$  from outside to inside of the membrane vesicle 33. Accordingly, the change of the  $H^+$  concentration outside and inside of the membrane vesicle 33, is approximately limited to that resulting from pyrophosphate included in the sample solution 32. Therefore, the amount of pyrophosphate included in the sample solution 32 can be accurately estimated.

#### 【0100】

Moreover, membrane of the membrane vesicle 33 may include proteins other than  $H^+$ -pyrophosphatase. However, these proteins are preferably proteins that do not react with pyrophosphate, or have low reactivity therewith. In other words, when pyrophosphate reacts with a protein, other than  $H^+$ -pyrophosphatase, which is present in the membrane of the membrane vesicle 33, the amount of pyrophosphate which reacts with  $H^+$ -pyrophosphatase is decreased, and concomitantly

thereto, the amount of transport of  $H^+$  is decreased. In addition, when a protein which does not react with pyrophosphate, but which executes transport of  $H^+$  via a reaction with other substance than pyrophosphate is included in the membrane of the membrane vesicle 33, it is preferred that the substance with which the protein reacts is scarcely included in the sample solution 32. Specifically, when ATPase, a protein which hardly reacts with pyrophosphate, and which executes transport of  $H^+$  via a reaction with ATP, is included in the membrane of the membrane vesicle 33, it is preferred to render the sample solution 32 scarcely including ATP.

#### 【O 1 O 1】

Exemplary pH sensitive pigment includes acridine orange. Further, exemplary membrane potential sensitive pigment includes Oxonol V. Both of these are extremely sensitive pigments on a slight change of pH or membrane potential. Accordingly, measuring of pyrophosphate with high sensitivity is enabled.

#### 【O 1 O 2】

Also, a device for measuring pyrophosphate shown in Fig. 5 may be used. As shown in Fig. 5, a device for measuring pyrophosphate 50 is equipped with a vessel 34, an electrode 35, an internal chamber 36 provided within the vessel 34. In the internal chamber 36, is formed a membrane 37 having indwelling  $H^+$ -pyrophosphatase, while the bottom of the inner chamber 36 is provided with a  $H^+$  sensitive electrode 38. The active site of  $H^+$ -pyrophosphatase which hydrolyzes pyrophosphate is exposed outside of the internal chamber 36.

#### 【O 1 O 3】

Upon injection of a sample solution 32 into the vessel 34, when pyrophosphate is present in the sample solution 32, the enzyme reaction of  $H^+$ -pyrophosphatase is caused. Hence, the  $H^+$  concentration of the solution in the internal region 39 of the internal chamber 36 separated with the membrane 37 is increased, whilst the  $H^+$  concentration outside of the internal chamber 36 is decreased. Thus, pyrophosphate can be qualitatively or quantitatively measured by electrically measuring the change of the  $H^+$  concentration using the electrode 35 and  $H^+$  sensitive electrode 38. The sample solution 32 is injected into the vessel 34 after reserving a solution, such as a buffer, which allows for the measurement of pH, in the vessel 34 and internal region 39 previously in this Embodiment, but not limited thereto. For example, the membrane 37 may be previously arranged on the  $H^+$  sensitive electrode 38 within the internal chamber 36, and the sample solution 32 may be then added to the vessel 34. By this operation, electrical measurement of the change of the  $H^+$  concentration

is enabled using the electrode 35 and the  $H^+$  sensitive electrode 38, upon injection of the sample solution 32 into the vessel 34, thereby the internal region 39 filled with components that permeate the membrane 37 in the sample solution 32 (i.e., the solution without including pyrophosphate).

**【O 1 O 4】**

Additionally,  $H^+$ -pyrophosphatase of which active site that hydrolyzes pyrophosphate is exposed to the internal region 39 may be included in the membrane 37. However, when the membrane 37 including  $H^+$ -pyrophosphatase of which active site that hydrolyzes pyrophosphate is exposed to the internal region 39 is used, it is preferred that the concentration of pyrophosphate in the internal region 39 is set to be lower than the concentration of pyrophosphate outside of the internal chamber 36. Most preferably, pyrophosphate is not included within the internal region 39. Thus, transport of  $H^+$  from the internal region 39 to outside of the internal chamber 36 decreases or arrests, thereby dominating the transport of  $H^+$  from outside of the internal chamber 36 into the internal region 39. Accordingly, the change of the  $H^+$  concentration outside of the internal chamber 36 and in the internal region 39 is approximately limited to that resulting from pyrophosphate included in the sample solution 32. Therefore, the amount of pyrophosphate included in the sample solution 32 can be accurately estimated.

**【O 1 O 5】**

Moreover, the membrane 37 may include proteins other than  $H^+$ -pyrophosphatase. However, these proteins are preferably proteins that do not react with pyrophosphate, or have low reactivity therewith. In other words, when pyrophosphate reacts with a protein, other than  $H^+$ -pyrophosphatase, which is present in the membrane 37, the amount of pyrophosphate which reacts with  $H^+$ -pyrophosphatase is decreased, and concomitantly thereto, the amount of transport of  $H^+$  is decreased. In addition, when a protein which does not react with pyrophosphate, but which executes transport of  $H^+$  via a reaction with other substance than pyrophosphate is included in the membrane 37, it is preferred that the substance with which the protein reacts is scarcely included in the sample solution 32. Specifically, when ATPase, a protein which hardly reacts with pyrophosphate, and which executes transport of  $H^+$  via a reaction with ATP, is included in the membrane 37, it is preferred to render the sample solution 32 scarcely including ATP.

**【O 1 O 6】**

Furthermore, the amount of pyrophosphate is electrically measured with the electrode 35 and the  $H^+$  sensitive electrode 38 in the

device for measuring pyrophosphate 50, but not limited thereto. For example, a solution including a pH sensitive pigment or a membrane potential sensitive pigment may be added to the internal region 39 of the internal chamber. Fluorescence intensity of the pH sensitive pigment or the membrane potential sensitive pigment is thereby altered concomitantly with increase of the internal  $H^+$  concentration. The amount of pyrophosphate can be measured by optically measuring the alteration of this fluorescence intensity.

**【O 1 0 7】**

As described hereinabove, shape of the membrane with indwelling  $H^+$ -pyrophosphatase for use in measuring the amount of pyrophosphate may be either spherical or planate. In other words, a condition may be just constituted in which all or almost all migration of  $H^+$  between two regions that are separated by the membrane with indwelling  $H^+$ -pyrophosphatase is effected by  $H^+$ -pyrophosphatase.

**【O 1 0 8】**

Next, the device for discriminating the sequence of a SNP site of a target DNA in a sample is explained. Fig. 6 is a schematic drawing showing the device for discriminating a sequence according to this Embodiment.

**【O 1 0 9】**

As is shown in Fig. 6, the device for discriminating a base base sequence 60 has a reaction means 51 equipped with a reaction section 51a for executing a primer extension reaction and a pyrophosphate measuring section 51b for measuring pyrophosphate; and an analysis means 52 for controlling the reaction section 51a and the pyrophosphate measuring section 51b, and analyzing the obtained result. Further, the reaction means 51 has a slot to which a tip 53 can be inserted for introducing a sample solution.

**【O 1 1 0】**

The reaction section 51a may be constituted such that it enables thermoregulation which is required for the primer extension reaction. For example, when a PCR method is employed as the primer extension reaction, the reaction section 51a preferably has a constitution equipped with a heater section and a programmed thermal control section which can control the temperatures of the sample solution within the tip 53 for introducing the sample solution, to be suited for: denaturation of the nucleic acid; annealing of the primer; and the primer extension reaction by polymerase, respectively, for a predetermined time period. Additionally, when an isothermal reaction such as in an ICAN method, LAMP method and the like is employed, the

reaction section 51a preferably has a constitution equipped with a heater section and a thermal control section capable of keeping a constant temperature (e.g., 65° C). In this Embodiment, the same constitution as a thermal cycler for use in a PCR method is adopted.

**【O 1 1 1】**

The constitution of the pyrophosphate measuring section 51b varies depending on the measurement means for measuring the change of the H<sup>+</sup> concentration. In instances where the change of the H<sup>+</sup> concentration is optically measured using a pigment such as a pH sensitive pigment or a membrane potential sensitive pigment as shown in Fig. 4 described above, the pyrophosphate measuring section 51b preferably has a constitution equipped with a light source section for excitation of the fluorescent pigment, and a fluorescence intensity measurement section for measuring the intensity of the generated fluorescence.

**【O 1 1 2】**

Moreover, in instances where the change of the H<sup>+</sup> concentration is electrically measured using an electrode as shown in Fig. 5 described above, the pyrophosphate measuring section 51b preferably has a constitution equipped with a contact section or a terminal that is capable of electrically connecting to the electrode 35 and the H<sup>+</sup> sensitive electrode 38, respectively; and an electric potential difference measurement section capable of measuring the electric potential difference between the electrode 35 and the H<sup>+</sup> sensitive electrode.

**【O 1 1 3】**

For introducing the sample solution, the tip 53 is equipped with a PCR chamber 73, the device for measuring pyrophosphate 50 shown in Fig. 5 as described above, a flow pass 74c that connects between the PCR chamber 73 and the device for measuring pyrophosphate 50.

**【O 1 1 4】**

The PCR chamber 73 is a chamber for carrying out PCR (primer extension reaction) in a sample solution containing a purified DNA, a typing primer, DNA polymerase and 4 kinds of dNTPs. In the PCR chamber 73 may be previously charged necessary reagents, respectively, or such reagents may be introduced immediately before inserting the tip into the device for discriminating a base sequence 60.

**【O 1 1 5】**

Since the device for measuring pyrophosphate 50 has the constitution as explained above, the explanation is now omitted. It is possible to use a device in which the change of the H<sup>+</sup> concentration is converted to an optical change or an electrical change, and can

sense thus resulting optical change or electrical change, instead of the device for measuring pyrophosphate 50.

**【O 1 1 6】**

The flow pass 74c is provided with a closing member and the structure is as follows. When the closing member is lifted up, the PCR chamber 73 and the device for measuring pyrophosphate 50 are sealed respectively. The closing member is constituted such that opening and closing is allowed by the reaction means 51 of the device for discriminating a base sequence 60 described above.

**【O 1 1 7】**

Furthermore, the analysis means 52 is connected to the reaction means 51, and may be specifically, a personal computer (PC) or the like.

**【O 1 1 8】**

Operations of the device for discriminating a base sequence 60 are as follows.

**【O 1 1 9】**

First, a tip 53 with a PCR chamber 73 to which a sample solution is introduced containing a target DNA having a SNP site, a typing primer, DNA polymerase and 4 kinds of dNTPs is provided.

**【O 1 2 0】**

Next, the tip 53 is inserted into a slot of a reaction means 51. As shown in Fig. 6, when the tip 53 is inserted into the slot of the reaction means 51, the tip 53 is disposed within the reaction means 51 such that the PCR chamber 73 is positioned within the reaction section 51a, and that the device for measuring pyrophosphate 50 is positioned within the pyrophosphate measuring section 51b, respectively.

**【O 1 2 1】**

Next, the reaction means 51 renders a primer extension reaction caused in the sample solution which has been introduced into the PCR chamber of the tip 53 through repeating the steps illustrated in Figs. 1 (b) to (d), and the steps illustrated in Figs. 2 (b) to (d) in the reaction section 51a. Number of times of repeating the steps illustrated in Figs. 1 (b) to (d), and the steps illustrated in Figs. 2 (b) to (d) described above is set in the analysis means 52 beforehand.

**【O 1 2 2】**

Next, when the steps illustrated in Figs. 1 (b) to (d), and the steps illustrated in Figs. 2 (b) to (d) are completed, the flow pass 74c of the tip 53 is opened by the reaction means 51, and thus the sample solution is introduced into the device for measuring pyrophosphate 50. The pyrophosphate measuring section 51b measures

the amount of pyrophosphate generated by the primer extension reaction. Because specific method of measuring is as described above, the explanation is now omitted.

**【0 1 2 3】**

Next, the analysis means 52 analyzes the result obtained from the pyrophosphate measuring section 51b to discriminate the base type of the SNP site of the target DNA in the sample.

**【0 1 2 4】**

Next, another tip 53a which can be used instead of the tip 53 is explained. Fig. 7 (a) is a top view schematically showing another tip according to this Embodiment, and Fig. 7 (b) is a cross sectional view along the line X-X depicted in Fig. 7.

**【0 1 2 5】**

As shown in Fig. 7 (a) and (b), the tip 53a is equipped with a sample injection port 70, a DNA extraction chamber 71, a DNA purification chamber 72, a PCR chamber 73, a device for measuring pyrophosphate 50, a flow pass 74a that connects the DNA extraction chamber 71 and the DNA purification chamber 72, a flow pass 74b that connects the DNA purification chamber 72 and the PCR chamber 73, and a flow pass 74 c that connects the PCR chamber 73 and the device for measuring pyrophosphate 50. In brief, the tip 53a has a constitution further comprising a sample injection port 70, a DNA extraction chamber 71, a DNA purification chamber 72, and flow passes 74a and 74b in addition to the tip 53 as illustrated in Fig. 6.

**【0 1 2 6】**

The sample injection port 70 links between outside and the DNA extraction chamber 71. A sample solution of a sample such as blood, saliva, hair, hair root or the like, which was subjected to a treatment with a drug solution, is injected from the sample injection port 70 to the DNA extraction chamber 71.

**【0 1 2 7】**

The DNA purification chamber 72 is a chamber in which a treatment with a drug solution is carried out for purifying the DNA to eliminate impurities. As a matter of course, it may have a constitution that is provided with a column for purifying the DNA.

**【0 1 2 8】**

The PCR chamber 73 is a chamber for carrying out PCR (primer extension reaction) in the sample solution containing the DNA purified in the DNA purification chamber 72, a typing primer, DNA polymerase and 4 kinds of dNTPs.

**【0 1 2 9】**

In the DNA extraction chamber 71, DNA purification chamber 72 and PCR chamber 73, may be previously charged necessary reagents, respectively, or such reagents may be introduced immediately before insertion into the device for discriminating a base sequence 60.

**【O 1 3 0】**

Since the device for measuring pyrophosphate 50 has the constitution as explained above, the explanation is now omitted. It is possible to use a device in which the change of the  $H^+$  concentration is converted to an optical change or an electrical change, and can sense thus resulting optical change or electrical change, instead of the device for measuring pyrophosphate 50.

**【O 1 3 1】**

The flow passes 74a, 74b and 74c are provided with a closing member 75. It has a structure to result in sealing of the DNA extraction chamber 71, the DNA purification chamber 72, the PCR chamber 73 and the device for measuring pyrophosphate 50, respectively, when each closing member 75 is lifted up. The closing member 75 is constituted such that opening and closing is allowed by the reaction means 51 of the device for discriminating a base sequence 60 described above.

**【O 1 3 2】**

Moreover, instead of the closing member 75, for example, a backflow prevention valve or the like may be disposed to the flow passes 74a, 74b and 74c. In addition, it may have such a constitution that the sample solution is transported to each section of the DNA extraction chamber 71, DNA purification chamber 72, PCR chamber 73 and device for measuring pyrophosphate 50, by: providing a deaerating opening that communicates to the device for measuring pyrophosphate 50; mounting an air discharge pump to the sample injection port 70; and mounting an air intake pump to the aforementioned deaerating opening. Further, the air discharge pump and the air intake pump described above may be constructed as a discharge and intake pump of oil that is nonmiscible to the sample solution. In every constitution, it is acceptable if sealing of the DNA extraction chamber 71, the DNA purification chamber 72, the PCR chamber 73 and the device for measuring pyrophosphate 50, in the reaction means 51 of the aforementioned device for discriminating a base sequence 60, respectively, is possible. Thus, the primer extension reaction and measuring of pyrophosphate can be carried out on a single tip although they require different conditions of the enzyme reaction (e.g., optimal temperature and the like).

**【O 1 3 3】**

Additionally, the DNA extraction chamber 71, the DNA purification chamber 72 and the PCR chamber 73 are separated to individualized chambers in the tip 53a of this Embodiment, however, it may be constituted such that extraction of a DNA, purification of a DNA and PCR are carried out in a single chamber.

**【0 1 3 4】**

Fig. 8 is a top view schematically showing another tip according to this Embodiment.

**【0 1 3 5】**

As is shown in Fig. 8, the tip 53b is, similarly to the tip 53a shown in Fig. 7, equipped with a sample injection port 70, a DNA extraction chamber 71, a DNA purification chamber 72, a PCR chamber 73, a device for measuring pyrophosphate 50, a flow pass 74a that connects between the DNA extraction chamber 71 and the DNA purification chamber 72, a flow pass 74b that connects between the DNA purification chamber 72 and the PCR chamber 73, and a flow pass 74 c that connects between the PCR chamber 73 and the device for measuring pyrophosphate 50. In particular, the flow pass 74b is bifurcated, and PCR chambers 73, devices for measuring pyrophosphate 50, and flow passes 74c that connect the PCR chamber 73 and the device for measuring pyrophosphate 50 are provided by two, respectively.

**【0 1 3 6】**

By introducing typing primers, which are different with each other, to the two PCR chambers 73 using the tip 53b, simultaneous discrimination of base types of two SNP sites is enabled.

**【0 1 3 7】**

Fig. 9 is a perspective view schematically showing still another tip (vertical tip) of this Embodiment.

**【0 1 3 8】**

As shown in Fig. 9, the tip 90 is equipped with a sample introduction section 91, a DNA purification section 92, a PCR section 93 and a device for measuring pyrophosphate 50.

**【0 1 3 9】**

The sample introduction section 91 has a sample introduction chamber 91a and a DNA extraction column 91b. A sample solution of a sample such as blood, saliva, hair, hair root or the like, which was subjected to a treatment with a drug solution as needed, is injected to the sample introduction chamber 91a, and passes through the DNA extraction column 91b. A liquid such as blood, saliva or the like may be injected to the sample introduction chamber 91a without any treatment with a drug solution.

**【0 1 4 0】**

The DNA purification section 92 has a DNA purification chamber 92a and a DNA purification column 92b. The sample solution after passing through the DNA extraction column 91b is introduced to the DNA purification chamber 92a, and subsequently, passes through the DNA purification column 92b.

**【0141】**

The PCR section 93 has a PCR chamber 93a and a separating member 93b. The sample solution including a DNA which was purified by passing through the DNA purification column 92b is introduced to the PCR chamber 93a, and thereto are added a DNA, a typing primer, DNA polymerase and 4 kinds of dNTPs. Accordingly, PCR (primer extension reaction) is caused.

**【0142】**

The separating member 93b is constituted such that it can be opened and closed by the reaction means 51 of the aforementioned device for discriminating a base sequence 60. When PCR is terminated in the PCR chamber 93a, the reaction means 51 renders the separating member 93b open, thereby allowing passage of the sample solution into the device for measuring pyrophosphate 50.

**【0143】**

Since the device for measuring pyrophosphate 50 has the constitution as explained above, the explanation is now omitted. It is possible to use a device in which the change of the  $H^+$  concentration is converted to an optical change or an electrical change, and can sense thus resulting optical change or electrical change, instead of the device for measuring pyrophosphate 50.

**【0144】**

Although the difference of progress of the primer extension reactions is analyzed by measuring the amount of pyrophosphate in this Embodiment, as a matter of course, the amount of pyrophosphate that is present in a sample solution can be measured accurately, with no limitation to the primer extension reaction.

**【0145】**

Further, in a primer extension reaction in particular, ATP and dATP become an inhibitor of  $H^+$ -pyrophosphatase, therefore, when ATP or dATP is present in the sample solution, and the amount of pyrophosphate is small, the  $H^+$  concentration is scarcely changed. To the contrary, when dATP in the sample solution is consumed by the primer extension reaction, and the amount of pyrophosphate is large, the  $H^+$  concentration is greatly changed. In brief, the difference of progress of the primer extension reactions can be measured as a

greater difference. Therefore, the base type can be discriminated with a higher degree of accuracy.

**【O 1 4 6】**

(Embodiment 2)

In this Embodiment, a method of discriminating as to whether or not a DNA having a particular base sequence is included in a sample, i.e., a method of detecting a DNA having a particular base sequence is explained. Specifically, methods in which a primer extension reaction (for example, an amplification reaction such as PCR method, ICAN method, LCR method, SDA method, LAMP method or the like) using 4 kinds of dNTPs is utilized is explained with reference to Fig. 10. Fig. 10 is a process drawing showing the method of discriminating as to whether or not a DNA having a particular base sequence is included in a sample according to this Embodiment.

**【O 1 4 7】**

In the method of this Embodiment, a primer having a base sequence which can complementarily bind to a DNA having a particular base sequence is used.

**【O 1 4 8】**

First, in the step illustrated in Fig. 10 (a), a primer 101 having a base sequence which can complementarily bind to a DNA having a particular base sequence, DNA polymerase 8 and 4 kinds of dNTPs are added to a solution to which discrimination is intended as to whether or not a DNA having a particular base sequence is included therein. Thus, a sample solution 100 is prepared. The primer 101 is designed such that it completely hybridizes to a single stranded DNA having the particular base sequence.

**【O 1 4 9】**

Next, in the step illustrated in Fig. 10 (b), a heat treatment of the sample solution 100 is carried out. Almost all DNA included in the sample solution 100 is thereby converted to the single stranded DNA.

**【O 1 5 0】**

Next in the step illustrated in Fig. 10 (c), the sample solution 100 is cooled. Accordingly, when a single stranded DNA 102 produced from the DNA having the particular base sequence is present in the sample solution 100, the primer 101 is hybridized to the single stranded DNA 102.

**【O 1 5 1】**

Next, in the step illustrated in Fig. 10 (d), the temperature of the sample solution 100 is regulated to an optimal temperature for the primer extension reaction. When the single stranded DNA 102 is

present, the primer 101 is hybridized to the single stranded DNA 102, resulting in the primer extension reaction. Accordingly, dNTP is consumed by the DNA polymerase 8, thereby producing pyrophosphate.

**【0152】**

In this step, when a single stranded DNA 102 having the particular base sequence is not present, the primer 101 can not achieve hybridization. Hence, the primer extension reaction does not occur. Therefore, dNTP is scarcely consumed, and pyrophosphate is hardly produced.

**【0153】**

Next, the presence/absence of progress of the primer extension reaction is discriminated by measuring the amount of pyrophosphate. Thus, it is discriminated that a DNA having a particular base sequence was not present in the sample. In summary, the presence/absence of a DNA having a particular base sequence can be discriminated. The method of measuring the amount of pyrophosphate of this Embodiment is just the same as the method in Embodiment 1 described above, therefore, the explanation is now omitted.

**【0154】**

As described hereinabove, the presence/absence of a nucleic acid having a particular base sequence in a sample can be discriminated by analyzing pyrophosphate that is produced in an amplification method of the nucleic acid having the particular base sequence in the sample, by way of analysis of the change of the  $H^+$  concentration using  $H^+$ -pyrophosphatase.

**【0155】**

It is possible to put the method of discriminating the presence/absence of a nucleic acid having a particular base sequence explained in this Embodiment into effect using the device for measuring pyrophosphate 50, the device for discriminating a base sequence 60, and the tip 53a, 53b or 90 which were explained in Embodiment 1 as described above.

**【0156】**

Although methods in which a primer extension reaction is utilized using 4 kinds of dNTPs are explained in the aforementioned Embodiments 1 and 2, as a matter of course, a primer extension reaction using one kind of dNTP (or ddNTP) can be also utilized, as explained with reference to Figs. 21 and 22 in connection with the conventional technology. In addition, an amplification method of a nucleic acid having a particular base sequence, such as PCR or the like, in which two or more kinds of primers including a typing primer are used may be employed in combination. In other words,

amplification of a nucleic acid having a base sequence including a SNP which is an object of analysis may be analyzed using  $H^+$ -pyrophosphatase to execute the discrimination of the base type of a SNP site.

**【0157】**

As a matter of course, according to the method of the Embodiment 1 described above, it is possible to discriminate not alone the base type of a SNP site, but a particular base sequence can be also discriminated.

**【0158】**

Additionally, in the Embodiments 1 and 2 described above, determination of the base type in a base sequence of a DNA and detection of DNA are explained, however, they are not limited to DNA, of course, but determination of the base type in a base sequence of an RNA and detection of RNA can be similarly performed. Furthermore, the sample which can be used includes any one irrespective of a single stranded DNA or a double stranded DNA.

**【0159】**

**【Example】**

**(Example 1)**

This Example was conducted according to the method of Shizuo Yoshida et al., (Masayoshi Maeshima and Shizuo Yoshida, 1989, J.Biol.Chem., 264(33), pp. 20068-20073) as demonstrated below.

**【0160】**

First, membrane vesicles comprising a tonoplast membrane derived from *Phaseolus aureus* was dissolved in a solution containing Tris/Mes buffer (concentration of 5 mM, pH 7.0), sorbitol (concentration of 0.25 M) and DTT (concentration of 2 mM) to give a suspension of membrane vesicles comprising a tonoplast membrane.

**【0161】**

Next, this suspension was mixed in a reaction liquid containing  $MgSO_4$  (concentration of 1 mM), KCl (concentration of 50 mM), sorbitol (concentration of 0.25 M), acridine orange (pH sensitive pigment, concentration of 3  $\mu M$ ), Hepes/Bristris propane (concentration of 25 mM, pH 7.2) to prepare a  $H^+$ -pyrophosphatase liquid.

**【0162】**

Next, this  $H^+$ -pyrophosphatase liquid was evenly dispensed into 4 tubes, and thereto was added a sodium pyrophosphate solution such that each final concentration of sodium pyrophosphate became 10  $\mu M$ , 20  $\mu M$ , 40  $\mu M$ , 60  $\mu M$ , 80  $\mu M$  and 100  $\mu M$ , respectively, to initiate the hydrolysis reaction of pyrophosphate by  $H^+$ -pyrophosphatase.

**【0163】**

In this Example, an excitation light of 493 nm was irradiated on each reaction liquid, and the change of fluorescence intensity at 540 nm before and after adding the sodium pyrophosphate solution was analyzed. The results are shown in Fig. 11.

【O 1 6 4】

Fig. 11 is a graph showing the relationship between the concentration of sodium pyrophosphate and the change of fluorescence intensity at 540 nm. In this Figure, the change of fluorescence intensity at 540 nm is represented by extinction coefficient per unit second in the reaction liquid that corresponds to each sodium pyrophosphate concentration. Further, extinction coefficient per unit second in the reaction liquid that corresponds to each sodium pyrophosphate concentration is converted, on the basis of the extinction coefficient per unit second in the reaction liquid having the final concentration of sodium pyrophosphate of 100  $\mu$ M assumed as 100%.

【O 1 6 5】

As is shown in Fig. 11, a result was obtained indicating that the extinction coefficient of acridine orange per 1 second is altered with a relationship with approximately hyperbolic function depending on the concentration of sodium pyrophosphate. Accordingly, it is revealed that pyrophosphate can be quantitatively detected by measuring the extinction coefficient of acridine orange per 1 second.

【O 1 6 6】

(Example 2)

This Example was conducted according to the method of Masasuke Yoshida et al., (MasaH.Sato, Masahiko Kasahara, Noriyuki Ishii, Haruo Homareda, Hideo Matsui and Masasuke Yoshida, 1994, J.Biol.Chem., 269(9), pp. 6725-6728) as demonstrated below.

【O 1 6 7】

First, purification of tonoplast membrane  $H^+$ -pyrophosphatase from seeds of squash was conducted.

【O 1 6 8】

Subsequently, a proteoliposome liquid of tonoplast membrane  $H^+$ -pyrophosphatase was prepared by adding tonoplast membrane  $H^+$ -pyrophosphatase obtained after purification into a lipid mixture that was prepared from phosphatidylcholine of soybean and cholesterol. After mixing this proteoliposome liquid in a reaction liquid containing sorbitol (concentration of 0.25 M), Tricine-Na (concentration of 10 mM, pH 7.5), EGTA (concentration of 0.1 mM), KCl (concentration of 50 mM) and Oxonol V (membrane potential sensitive

pigment, concentration of  $0.2 \mu\text{M}$ ), the mixture was evenly dispensed into 5 tubes.

**【0169】**

Subsequently, to the 5 tubes was added a sodium pyrophosphate solution such that final concentration of sodium pyrophosphate became  $10 \mu\text{M}$ ,  $20 \mu\text{M}$ ,  $40 \mu\text{M}$ ,  $60 \mu\text{M}$ ,  $80 \mu\text{M}$  and  $100 \mu\text{M}$ , respectively, to initiate the hydrolysis reaction of pyrophosphate by  $\text{H}^+$ -pyrophosphatase.

**【0170】**

In this Example, an excitation light of  $610 \text{ nm}$  was irradiated on each reaction liquid, and alteration of membrane potential of proteoliposome included in each reaction liquid before and after adding the sodium pyrophosphate solution was analyzed by measuring the change of fluorescence intensity at  $639 \text{ nm}$  before and after adding the sodium pyrophosphate solution. The results are shown in Fig. 12.

**【0171】**

Fig. 12 is a graph showing the relationship between the concentration of sodium pyrophosphate and the change of fluorescence intensity at  $639 \text{ nm}$ . In this Figure, the change of fluorescence intensity at  $639 \text{ nm}$  is represented by extinction coefficient per unit second in the reaction liquid that corresponds to each sodium pyrophosphate concentration. Further, extinction coefficient per unit second in the reaction liquid that corresponds to each sodium pyrophosphate concentration is converted, on the basis of the extinction coefficient per unit second in the reaction liquid having the final concentration of sodium pyrophosphate of  $100 \mu\text{M}$  assumed as 100%.

**【0172】**

As is shown in Fig. 12, a result was obtained indicating that the extinction coefficient of Oxonol V per 1 second is altered with a relationship with approximately hyperbolic function depending on the concentration of sodium pyrophosphate. Accordingly, it is revealed that pyrophosphate can be quantitatively detected by measuring the extinction coefficient of Oxonol V per 1 second.

**【0173】**

(Example 3)

This Example was conducted according to the method disclosed in Patent Publication No. 3213341.

**【0174】**

First, similarly to Example 2 described above, a lipid bilayer including tonoplast membrane  $\text{H}^+$ -pyrophosphatase was fixed on a commercially available ISFET-pH sensor using tonoplast membrane  $\text{H}^+$ -pyrophosphatase derived from seeds of squash. It should be noted however that outside of the lipid bilayer was filled with a reaction

solution containing  $\text{MgSO}_4$  (concentration of 1 mM), KCl (concentration of 50 mM), sorbitol (concentration of 0.25 M), Hepes/Bistris propane (concentration of 25 mM, pH 7.2).

【0175】

Next, using the aforementioned ISFET-pH sensor with the fixed lipid bilayer including tonoplast membrane  $\text{H}^+$ -pyrophosphatase, each pH value was measured in instances where a sodium pyrophosphate solution was added such that final concentration of sodium pyrophosphate in the aforementioned reaction solution became 20  $\mu\text{M}$ , 40  $\mu\text{M}$ , 60  $\mu\text{M}$ , 80  $\mu\text{M}$  and 100  $\mu\text{M}$ , respectively. The results are shown in Fig. 13.

【0176】

As is shown in Fig. 13, a result was obtained indicating that the pH value is decreased depending on the concentration of sodium pyrophosphate. Accordingly, it is revealed that pyrophosphate can be quantitatively detected by measuring the pH value.

【0177】

(Example 4)

In this Example, detection of  $\lambda$  DNA (with regard to entire base sequence of  $\lambda$  DNA, see, Accession No. V00636, J02459, M17233 and X00906 of GenBank database) in a sample was conducted.

【0178】

First, a sample liquid A containing  $\lambda$  DNA (manufactured by Takara Shuzo Co., Ltd.) at the concentration of 10 ng/ $\mu\text{L}$  dissolved in distilled water, and a sample liquid B consisting of distilled water alone were provided. Also, as shown in Fig. 14 (a), primer solutions E and F containing two kinds of primers C and D, which can completely hybridize to a particular base sequence of  $\lambda$  DNA, dissolved in distilled water (20  $\mu\text{M}$  each), respectively, were provided.

【0179】

To the aforementioned sample liquids A and B were respectively added TaKaRa La Taq (5 U/ $\mu\text{L}$ , manufactured by Takara Shuzo Co., Ltd.), 2  $\times$  GC buffer I that is a buffer for exclusive use of TaKaRa La Taq (manufactured by Takara Shuzo Co., Ltd.), a dNTP mixture (each concentration of 2.5mM, manufactured by Takara Shuzo Co., Ltd.), and primer solutions E and F to prepare the PCR reaction liquids G and H having the composition presented in Fig. 14 (b).

【0180】

Next, for each of the PCR reaction liquids G and H, a PCR reaction was conducted under the reaction temperature conditions presented in Fig. 14 (c).

【0181】

After terminating the PCR reaction, each of the PCR reaction liquids G and H was mixed with the  $H^+$ -pyrophosphatase liquid described in the above Example 1 to subject to a reaction.

【O 1 8 2】

In this Example, the change of fluorescence intensity of acridine orange before and after mixing the  $H^+$ -pyrophosphatase liquid was analyzed for each of the PCR reaction liquids G and H. For the analysis of fluorescence intensity of acridine orange, an excitation light of 493 nm was irradiated, and the analysis was performed with respect to fluorescence intensity at 540 nm. The results are shown in Fig. 15 (a).

【O 1 8 3】

Fig. 15 (a) illustrates the percentage change of fluorescence intensity before and after mixing the  $H^+$ -pyrophosphatase liquid to each of the PCR reaction liquids G and H, respectively. The percentage change of fluorescence intensity is represented by the formula shown in Fig. 15 (b).

【O 1 8 4】

As is shown in Fig. 15 (a), the percentage change of fluorescence intensity of the PCR reaction liquid G is evidently greater than that of the PCR reaction liquid H. In other words, it is revealed that the primer extension reaction proceeded. Accordingly, it is revealed that a target nucleic acid can be detected by measuring the fluorescence intensity of acridine.

【O 1 8 5】

(Example 5)

In this Example, mutant  $\lambda$  DNA involving an artificial substitution of a certain base in the base sequence of  $\lambda$  DNA into other base was generated, and studied as to whether or not discrimination can be executed between normal  $\lambda$  DNA and the mutant  $\lambda$  DNA.

【O 1 8 6】

First, the mutant  $\lambda$  DNA was generated using  $\lambda$  DNA (manufactured by Takara Shuzo Co., Ltd.). A GC base pair (in the Figure, region  $R_1$ ) in  $\lambda$  DNA illustrated in Fig. 16 (hereinafter, normal  $\lambda$  DNA is described as wild type  $\lambda$  DNA), which is present in the double stranded DNA sequence was artificially substituted with an AT base pair (in the Figure, region  $R_2$ ) by a well known method to persons skilled in the art to give the mutant  $\lambda$  DNA.

【O 1 8 7】

Next, the wild type  $\lambda$  DNA and mutant  $\lambda$  DNA were dissolved in distilled water to give the final concentration of 10 ng/ $\mu$ L,

respectively, to prepare a wild type  $\lambda$  DNA liquid and a mutant  $\lambda$  DNA liquid, respectively.

**【O 1 8 8】**

Next, in order to discriminate the difference of the bases described above, a typing primer illustrated in Fig. 16 (a) was provided. Subsequently, a typing primer solution was prepared by dissolving the typing primer in distilled water to give the final concentration of 20  $\mu$ M.

**【O 1 8 9】**

The typing primer illustrated in Fig. 16 (a) completely hybridizes to the single stranded DNA described in the lower panel of wild type  $\lambda$  DNA. However, the base G at 3' end of this typing primer can not hybridize to the single stranded DNA described in the lower panel of mutant  $\lambda$  DNA. Therefore, when the primer extension reaction is executed using this typing primer, the reaction satisfactorily proceeds in the instance of wild type  $\lambda$  DNA, however, the reaction does not proceed well in the instance of mutant  $\lambda$  DNA.

**【O 1 9 0】**

Also, the primer solution F used in the aforementioned Example 4 was provided.

**【O 1 9 1】**

Next, for each of the wild type  $\lambda$  DNA liquid and the mutant  $\lambda$  DNA liquid, the PCR reaction liquids I and J having the composition presented in Fig. 16 (b) were prepared using TaKaRa Taq (5 U/ $\mu$ L, manufactured by Takara Shuzo Co., Ltd.), 10  $\times$  PCR buffer that is for exclusive use of TaKaRa Taq (manufactured by Takara Shuzo Co., Ltd.), a dNTP mixture (each concentration of 2.5 mM, manufactured by Takara Shuzo Co., Ltd.), and the typing primer solution and the primer solution F.

**【O 1 9 2】**

Next, in the PCR reaction liquids I and J, a PCR reaction was conducted, respectively, under the reaction temperature conditions presented in Fig. 16 (c).

**【O 1 9 3】**

After terminating the PCR reaction, the PCR reaction liquids I and J were respectively mixed with the  $H^+$ -pyrophosphatase  $\cdot$  liposome liquid to subject to a reaction. The  $H^+$ -pyrophosphatase  $\cdot$  liposome liquid was prepared according to the method of Masasuke Yoshida et al, (MasaH. Sato, Masahiko Kasahara, Noriyuki Ishii, Haruo Homareda, Hideo Matsui and Masasuke Yoshida., 1994, J.Biol.Chem., 269(9), pp. 6725-6728).

**【O 1 9 4】**

Specifically, purification of tonoplast membrane  $H^+$ -pyrophosphatase from seeds of squash was first conducted. Subsequently, a proteoliposome liquid of tonoplast membrane  $H^+$ -pyrophosphatase was prepared by adding tonoplast membrane  $H^+$ -pyrophosphatase obtained after purification into a lipid mixture that was prepared from phosphatidylcholine of soybean and cholesterol. This proteoliposome liquid was mixed in a reaction liquid containing sorbitol (concentration of 0.25 M), Tricine-Na (concentration of 10 mM, pH 7.5), EGTA (concentration of 0.1 mM), KCl (concentration of 50 mM) and Oxonol V (membrane potential sensitive pigment, concentration of 0.2  $\mu$ M), to give a  $H^+$ -pyrophosphatase - liposome liquid.

【O 1 9 5】

In this Example, an excitation light of 610 nm was irradiated on each PCR reaction liquid, and alteration of membrane potential of proteoliposome included in each reaction liquid was analyzed by measuring the change of fluorescence intensity at 639 nm of Oxonol V before and after adding the sodium pyrophosphate solution. The results are shown in Fig. 17.

【O 1 9 6】

Fig. 17 illustrates the percentage change of fluorescence intensity before and after mixing of the PCR reaction liquids I and J, respectively. As is shown in Fig. 17, the percentage change of fluorescence intensity of the PCR reaction liquid I is evidently greater than that of the mutant PCR reaction liquid J. The grounds therefore are believed that the PCR reaction did not proceed well in the PCR reaction liquid J, however, the reaction satisfactorily proceeded in the PCR reaction liquid I, and consequently, thus produced pyrophosphate reacted with  $H^+$ -pyrophosphatase that was present in liposome, leading to the transport of  $H^+$  into liposome.

【O 1 9 7】

Therefore, according to this Example, it is proven that a difference of a single base pair in a particular base sequence of DNA can be discriminated. In other words, it is suggested that the method of this Example is extremely effective for discriminating the base type of a SNP site, and for discriminating a particular base type such as mutation of a single base pair caused by a discontinuous variation.

【O 1 9 8】

(Example 6)

In this Example, unlike the Example 5 described above, possible discrimination of the difference of a single base pair between wild type  $\lambda$  DNA and mutant  $\lambda$  DNA was studied with a method of combination of a 1 base extension reaction and a reaction of  $H^+$ -pyrophosphatase.

**【0199】**

First, a wild type  $\lambda$  DNA (5 mM) liquid and a mutant  $\lambda$  DNA (5 mM) liquid were prepared by dissolving the same wild type  $\lambda$  DNA and mutant  $\lambda$  DNA as those used in the aforementioned Example 5 in distilled water to give the final concentration of 5 mM.

**【0200】**

Next, the primer illustrated in Fig. 18 (a) was provided. This primer can completely hybridize to the single stranded DNA shown in the lower panel of wild type  $\lambda$  DNA which is illustrated in Fig. 16 (a) in Example 5, at the sequence other than the base C at its 5' end. In other words, similarly to the single stranded DNA sequence shown in the lower panel of the mutant  $\lambda$  DNA sequence demonstrated in Example 5, it can completely hybridize to the sequence other than the base T at its 5' end.

**【0201】**

Next, a primer solution M was prepared in which this primer was dissolved in distilled water to give the final concentration of 0.2 mM.

**【0202】**

Subsequently, for each of the wild type  $\lambda$  DNA (5 mM) liquid and the mutant  $\lambda$  DNA (5 mM) liquid, the extension reaction liquids K and L having the composition presented in Fig. 18 (b) were prepared using TaKaRa Taq (5 U/ $\mu$ L, manufactured by Takara Shuzo Co., Ltd.) and 10  $\times$  PCR buffer that is for exclusive use of TaKaRa La Taq (manufactured by Takara Shuzo Co., Ltd.), and a 2.5 mM dATP solution and the primer solution M.

**【0203】**

Subsequently, for each of the extension reaction liquids K and L, a single base extension reaction was conducted under the reaction temperature conditions presented in Fig. 18 (c).

**【0204】**

After terminating the single base extension reaction, each extension reaction liquid was introduced to a modified ISFET electrode including  $H^+$ -pyrophosphatase fixed thereto. The modified ISFET electrode was that used in the aforementioned Example 3.

**【0205】**

Using this modified ISFET electrode, each pH value was measured in the instance of each extension reaction liquid was added. As a result, the pH of the extension reaction liquid K was 6.89, whilst the pH of the extension reaction liquid L was 6.02. Grounds for this result are believed that the extension reaction did not occur in the extension reaction liquid K containing wild type  $\lambda$  DNA, whilst the single base extension reaction by dATP occurred in the extension

reaction liquid L containing mutant  $\lambda$  DNA, and consequently, thus produced pyrophosphate reacted with  $H^+$ -pyrophosphatase on the modified ISFET electrode, leading to the transport of  $H^+$  to the modified ISFET electrode side.

**【O 2 0 6】**

According to this method, it is proven that a difference of a single base pair in a base sequence of a target nucleic acid can be discriminated. In other words, it is revealed that this method is an extremely effective method for discriminating the base type of a SNP site, and for discriminating a particular base sequence such as substitution of a single base pair caused by a discontinuous variation.

**【O 2 0 7】**

**【EFFECT OF THE INVENTION】**

According to the present invention, a convenient technique for measuring pyrophosphate, and a technique for detecting or discriminating target nucleic acid can be provided.

**【DOCUMENT TITLE】 ABSTRACT**

**【ABSTRACT】**

**【PROBLEM TO BE SOLVED】** To provide a convenient technique for measuring pyrophosphate, a technique for detecting target nucleic acid, and a technique for discriminating a base type of the base sequence of the target nucleic acid.

**【SOLUTION】**  $H^+$ -pyrophosphatase is used to measure the amount of pyrophosphate. As is shown in Fig. 3,  $H^+$ -pyrophosphatase 11 has a property to transport  $H^+$  from the outside of the tonoplast membrane 13 that does not pass or hardly passes  $H^+$ , toward the inside of the tonoplast membrane, accompanied by a hydrolysis reaction that produces two molecules of phosphoric acid 12 from one molecule of pyrophosphate 10. Thus, by the enzyme reaction of  $H^+$ -pyrophosphatase, the  $H^+$  concentration is increased within the tonoplast membrane, while the  $H^+$  concentration is decreased outside of the tonoplast membrane. In the present invention, a sample solution containing pyrophosphate is brought into contact with  $H^+$ -pyrophosphatase in a state indwelling in a tonoplast membrane which had been isolated from a plant or the like. Thereafter, the change of the  $H^+$  concentration of either inside of the tonoplast membrane or outside of the tonoplast membrane is measured. Thus, the amount of pyrophosphate in the sample solution is measured, and then the difference in progress of the extension reactions of a primer shown in Fig. 1 (d) and Fig. 2 (d) is analyzed. The base type of a SNP site in a sample solution is discriminated by the analysis of the difference in progress of the extension reaction of a primer.

**【REPRESENTATIVE FIGURE】** Fig. 3
